Abstract

A general and convenient method for prepatation of N1-alkyl and N1-allylphenylhydrazones is described and their reactivity towards ketene is studied.

Introduction

In continuation of our interest on the reaction on imines with ketenes [1], we needed substantial amounts of N1-substituted phenylhydrazones. In preparation of N1-alkyl or N1-allylphenylhadrazones, however, we found out that no convenient synthetic method is available. There are spread reports in the literature and in most cases two steps sequence $(1 \rightarrow 2 \rightarrow 4)$ (schemel) utilized for the synthesis of N1-substituted phenylhydrazones [2,3]. The synthesis of N1 alkylphenylhydrazones by this method is problematic for several reasons. First, since both hydrazine(1) and (2) are liquid with similar physical properties, separtion and purification of N1-alkyphenylhydrazine

from the reaction mixture is difficult and resulting in low yield. Another problem in the synthesis of (4) by this route is that condensation of N1-alkylphenylhydrazine (2) with aldehydes and ketones, when comparing with simple non-alkylphenylhydrazine is rather difficult. Steric factor caused by substitution at N1 position may be responsible for this low reactivity.

Results and Discussion

Alternative method, i. e. $1 \rightarrow 3 \rightarrow 4$ is, to our knowledge, the simplest route for preparation of compounds (4). In 1990 Sherma er. al. reported the prepatation of only N-Methylphenylhydrazone by this method, claiming quantitative yield[4]. We repeated Sherma procedure several times, but the yields obtained were hardly more than 40 percent. By changing the reaction condition (see experimental section) we were able to alkylate phenylhydrazone (3) with various alkyl and allylhalide in good yields (table 1).

In preparation of hydrazone (4a-h), (3a-h) were treated with sodium amide in tetrahydrofuran (THF) to give corresponding anions. When these anions allowed to react in situ with appropriate alkyl hakide, N1-alkylated hydrazones (4a-h) were formed in good yied and good purity. No by - products were detected and work-up condition were straight forward. THF may be replaced by dimethoxyethane as solvent without appreciable loss in yield and purity. However, sodium n-buthylithium as deprotonationg agent. Alkyl iodide; bromide or chloride afforded comparable yields.

In pursuing our interest, the next step was to examine the reactivity of hydrazones with ketene. These reactions should be of interest, since they could lead either to β -lactam rings[1] or acetylhydrazones.

Addition of ketence, produced by pyrolysis of acetone at 700-750C, to phenylhdrazones (3a-e) gave N1-acetyl phenylhydrazones (6a-e) in high yield (table 2).

a: To compare melting points with hydrazones obtained from the ketene reaction.

N¹-Alkylphenylhydrazones, however, were not reactive toward ketene. Prolong treatment of hydrazone (4a, b, c, e) with ketene led to almost pure starting material.

Experimental Section

Melting points are uncorrected. ¹H-NMR spectra were recorded on a Varian T-60 spectrometer. Tetrahydrofuran was dried with sodium and distilled prior to use. Microanalysis were performed by Food Research Institue, Norwich-England. Infrared spectra were recorded using the nujol mull technique on a Beckmann Acculab 3 spectrometer. Mass spectra were taken by varian Mat 311 instrument.

Perparation of N¹-alkyl-1-phenylhydrazone(4a-h).

Typical Procedure*

Benzaldehyde methyphenydrazone (4a). To the

solution of sodium amide (2g, 0.05mole) in benzaldehyde added was (lm() lhydrazone(3a) (5.9g, 0.03 mole) in THF (20ml) -6C, whereupon a persistent orange colour solution was collected by illitation. The red.

he solution was stirred for one hour and the flue nitrogen gas was intensified to remove all onium formed in solution. The nitrogen flue, then, ped and methyl iodide (8.5g, 0.06mole) in THF (10ml) was added dropwise to the solution at 10-15C. At the end of the addition, solution became colourless and the reaction mixture was stirred at room temperature for one hour. Weter (50ml) was added to the solution and layers were sepatated. The organic layer was dried over sokium sulphate. Filtration and concentatuion of the filtrate by cooling gave a white crystals of (4a) (90%).

^{*} For physical and spectral data for the new compounds (6) see table 3 and 4 respectively.

Perparation of 1-acetyl-l-phenylhydrazones(6a-e) by the reaction of acetic anhydride with hydrazones(5)

Typical Procedure*

Acetic acid benzylidene phenylhydrazide(6a).- To phenylhydrazone(5a) (1g, 0.005mol) in glacial acetic acid (10ml) was added acetic anhydride (1g, 0.01mole) at room temperature. The reaction mixture was heated under reflux for 3 hours. The solvent and excess acetic

anhydride were evaporated in vaccuo and the residue was washed with distilled water (10ml). The solid was dissolved in ether (20ml) and sodium sulphate was then added and after stirring for few minutes the solution was collected by filtration. The filtrate was concentrated to 10 ml and cooled in an ice bath to give (6a) as a white crystalls (0.65g, 85%).

* For physical and spectral data see table 3 and 5.
